ABSTRACT

In recent years, researchers have obtained impressive reconstructions of the refractive index (RI) of biological objects through the combined use of advanced physics (nonlinear forward model) and regularization. Here, we propose an adaptation of these techniques for the more challenging problem of intensity-only measurements. It involves a difficult nonconvex optimization problem where phase and distribution of the RI must be jointly estimated. Using an adequate splitting, we leverage recent achievements in phase retrieval and RI reconstruction to perform this task. This yields an efficient reconstruction method with sparsity constraints.

Index Terms— Beam propagation, intensity measurement, coherence tomography, image reconstruction.

1. INTRODUCTION

Having access to the map of the refractive index (RI) of biological samples has a broad range of applications [1]. It can be obtained through optical diffraction tomography (ODT). There, the sample is illuminated by a set of tilted incident waves and holographic measurements of the resulting scattered fields are recorded (see Figure 1). The RI distribution is then recovered by solving an inverse scattering problem.

Pioneering works to solve the recovery problem were relying on direct linear inversion algorithms such as back-propagation [2, 3]. Reconstructions were then dramatically improved using regularization-based methods [4, 5]. However, the validity of linear models is restricted to weakly scattering samples. To overcome this limitation, the most recent reconstruction algorithms combine advanced physical models with modern regularization [6, 7]. These methods account for multiple scattering, which opens the door to the imaging of strongly scattering objects.

As a CCD camera can measure intensity only, holographic measurements must be acquired using an elaborate interferometric setup that needs a reference beam or multiple measurements per angle. Phaseless diffraction tomography allows one to simplify this setup by recording a single intensity measurement per angle. However, this comes at the price of a more challenging inverse problem. Existing methods tackle this difficulty by alternating between phase retrieval and RI estimation. The phase estimation step is generally performed using the popular Gerchberg-Saxton projection [8]. The RI reconstruction step has known the same progression as for classical ODT, going from linear models [9, 10] to nonlinear ones with ad hoc regularization [11, 12, 13].

Contributions In this paper, we propose phaseless diffraction tomography as an adaptation of the efficient regularized method [6] that solves inverse scattering. We thereby leverage the benefit of an advanced nonlinear physical model and sparse regularization. We first express the inverse problem within a variational framework that includes the total variation (TV) penalty together with a nonnegativity constraint. Then, using an adequate splitting strategy, we carry out the optimization by alternating between simpler steps. For each subproblem, we deploy an efficient numerical solution. Finally, we validate the proposed method on simulated and experimental data.

2. BEAM-PROPAGATION METHOD

We consider the 2D area $\Omega$ discretized in $(N_x \times N_z)$ points with steps $\delta x$ and $\delta z$. We denote the RI distribution of the sample by $n \in \mathbb{R}^{N_x \times N_z}$ and the RI of the surrounding medium by $n_b \in \mathbb{R}$. Also, we introduce the RI variation $\delta n = (n - n_b)1$ with $1 = \sum_{k=1}^{N_x N_z} e_k$. The incident plane wave of wavelength $\lambda$ is referred to as $u_{\text{inc}} \in \mathbb{C}^{N_x \times N_z}$. We represent the total field $u_{\text{tot}}(\delta n) \in \mathbb{C}^{N_x \times N_z}$ (incident + scattered) as

$$u_{\text{tot}}(\delta n) = a_q(\delta n) e^{i k_b q}, \quad (1)$$
where \( a(\delta n) \in \mathbb{C}^{N_x \times N_z} \) is the complex envelope of the wave, \( k_b = \frac{2\pi n_b}{\lambda} \) is the background wavenumber, and the index \( q \) denotes the \( z \) slice of the corresponding matrix. The beam-propagation method (BPM) computes \( a(\delta n) \) slice-by-slice along the optical axis \( z \) using the recursive relation

\[
a_q(\delta n) = (a_{q-1}(\delta n) * h_{\text{prop}}) \odot p_q(\delta n), \quad (2)
\]

\[
a_0(\delta n) = u_0^{\text{in}}, \quad (3)
\]

where \( \odot \) denotes the Hadamard product and * the convolution operation. In (2), \( a_{q-1}(\delta n) \) is first propagated to the next slice by convolution with the propagation kernel \( h_{\text{prop}} \in \mathbb{C}^{N_z} \) given by

\[
h_{\text{prop}} = \mathcal{F}^{-1}\left\{ \exp\left( -\frac{j\omega^2\delta z}{k_b + \sqrt{k_b^2 - \omega^2}} \right) \right\} \quad \text{(diffraction step),} \quad (4)
\]

where \( \mathcal{F} \) is the 1D discrete Fourier transform, \( \omega \in \mathbb{R}^{N_z} \) is the frequency variable for the \( x \) direction, and all operations are component-wise. This convolution is followed by a point-wise multiplication with the \( q \)th slice of the phase mask \( p(\delta n) \in \mathbb{C}^{N_x \times N_z} \) defined as

\[
p_q(\delta n) = \exp\left( jk_0\delta z(\delta n)_q \right) \quad \text{(refraction step),} \quad (5)
\]

where \( k_0 = k_b/n_b \) is the wavenumber in free space. Finally, the BPM forward model is defined by the operator

\[
B : \mathbb{R}^{N_x \times N_z} \rightarrow \mathbb{C}^{N_x}
\delta n \mapsto a_{N_x}(\delta n) e^{j k_b N_z}, \quad (6)
\]

where \( a_{N_x}(\delta n) \in \mathbb{C}^{N_x} \) is computed using (2)-(3).

3. ADMM-BASED RECONSTRUCTION

We denote by \( P \) the number of the incident planes waves \( u_{p}^{\text{in}} \forall p \in [1 \ldots P] \). The forward model that links \( \delta n \) to the intensity measurements \( y_p \in \mathbb{R}^{N_x} \) is

\[
y_p = |B_p(\delta n)|^2 + s_p \forall p \in [1 \ldots P], \quad (7)
\]

where \( s_p \in \mathbb{R}^{N_x} \) is a vector of noise components, \( |\cdot| \) denotes the component-wise magnitude, \((\cdot)^2\) denotes the component-wise square operation, and \( B_p \) is the BPM model in (6) associated to \( u_p^{\text{in}} \). To recover the RI variation \( \delta n \), we minimize the TV-regularized negative-log-likelihood of the noise distribution

\[
\hat{\delta n} \in \left\{ \arg\min_{\delta n \in \mathbb{R}^{N_x \times N_z}} \left( \frac{1}{2} \sum_{p=1}^{P} \| B_p(\delta n) - y_p \|_{\mathbf{W}_p}^2 + \tau \| \delta n \|_{TV} \right) \right\}, \quad (8)
\]

with \( \tau \) a regularization parameter, \( \chi \subseteq \mathbb{R}^{N_x \times N_z} \) a set that enforces the nonnegativity constraint, \( \mathbf{W}_p = \text{diag}(w_1^p, \ldots, w_{N_x}^p) \in \mathbb{R}^{N_x \times N_x} \) a diagonal matrix, and \( \| \cdot \|_{TV} \) a weighted \( \ell_2 \)-norm such that \( \|y\|_{\mathbf{W}} = \sum_{n=1}^{N_x} w_n^p (y_n)^2 \). To account for shot noise (Poisson), we set these weights to the inverse of the intensity of each measurement.

We then apply the popular alternating direction method of multipliers (ADMM) [14] strategy to solve our inverse problem. The leading idea is to split the initial problem in a series of simpler subproblems for which we can deploy efficient algorithms. Starting from

Algorithm 1 ADMM for minimizing (10)

Require: \( \{y_p\}_{p \in [1 \ldots P]}, \delta n^{(0)} \in \mathbb{R}^{N_x \times N_z}, \rho > 0, \tau > 0 \)
1: \( w_p^{(0)} = 0 \forall p \in [1 \ldots P] \)
2: \( k = 0 \)
3: while (not converged) do
4: \( y_p^{(k+1)} = \text{prox}_\frac{\tau}{2} \|y_p - B_p(\delta n^{(k)})\|_{\mathbf{W}_p}^2 (B_p(\delta n^{(k)}) + \frac{w_p^{(k)}}{\rho}) \)
5: \( \delta n^{(k+1)} = \arg\min_{\delta n \in \chi} \left( \frac{1}{2} \sum_{p=1}^{P} \| B_p(\delta n) - y_p^{(k+1)} \|_{\mathbf{W}_p}^2 + \frac{w_p^{(k)}}{\rho} \left\| \delta n \right\|_{TV} \right) \)
6: \( w_p^{(k+1)} = w_p^{(k)} + \rho (B_p(\delta n^{(k+1)}) - y_p^{(k+1)}) \forall p \in [1 \ldots P] \)
7: \( k \leftarrow k + 1 \)
8: end while
9: return \( \delta n^{(k)} \)

(8), we introduce the auxiliary variables \( v_p \in \mathbb{C}^{N_x} \forall p \in [1 \ldots P] \) to obtain the equivalent constrained problem

\[
\hat{\delta n} \in \arg\min_{\delta n \in \chi} \left( \frac{1}{2} \sum_{p=1}^{P} \| v_p \|_{\mathbf{W}_p}^2 - y_p \|_{\mathbf{W}_p}^2 + \tau \| \delta n \|_{TV} \right),
\]

s.t. \( v_p = B_p(\delta n) \forall p \in [1 \ldots P] \). \quad (9)

This problem admits the augmented-Lagrangian form

\[
L(\delta n, v_1, \ldots, v_P, w_1, \ldots, w_P) = \frac{1}{2} \sum_{p=1}^{P} \| v_p \|_{\mathbf{W}_p}^2 - y_p \|_{\mathbf{W}_p}^2 + \frac{\rho}{2} \| B_p(\delta n) - v_p + w_p / \rho \|_{TV}^2 + \tau \| \delta n \|_{TV},
\]

where \( w_p \) and \( \rho \) are the Lagrangeans and the penalty parameter [14]. Algorithm 1 shows the steps to minimize (10) using ADMM.

3.1. Proximity Operator

At Step 4 of Algorithm 1, one has to compute the proximity operator of \( D(v) = \frac{1}{2} \| v^2 - y_p \|_{\mathbf{W}_p}^2 \) defined as

\[
\text{prox}_D(x) = \arg\min_{v \in \mathbb{C}^{N_x}} \left( \frac{1}{2} \| v - x \|_{\mathbf{W}}^2 + D(v) \right).
\]

Here, we take advantage of the closed-form expressions that have been recently derived for both Gaussian and Poisson likelihoods in [15]. Specifically, the proximity operator in (11) is computed component-wise according to

\[
q(x) = \frac{4m_p x}{\rho} + \rho \left( 1 - \frac{4m_p}{\rho} \right) |x_m|,
\]

which is found with Cardano’s method.

3.2. Solving for \( \delta n \)

At Step 5 of Algorithm 1, we need to reconstruct the RI distribution from the complex “data” \( z_p^{(k+1)} = v_p^{(k+1)} + w_p^{(k)}/\rho \), taking into account that

\[
\delta n^{(k+1)} = \arg\min_{\delta n \in \chi} \left( \frac{1}{2} \sum_{p=1}^{P} \| B_p(\delta n) - z_p^{(k+1)} \|_{\mathbf{W}_p}^2 + \tau \| \delta n \|_{TV} \right).
\]

1269
This optimization problem is solved using the fast iterative shrinkage-thresholding algorithm (FISTA) [16], which has already been proven to be useful in this context [17, 6]. Two quantities are required

1. The proximity operator of \( \frac{\tau}{p} \cdot \| \cdot \|_{TV} \) which is computed efficiently using a standard iterative method [6].

2. The gradient of \( \mathcal{F}(\delta n) = \frac{1}{2} \sum_{p=1}^{P} \| \mathbf{H}_p(\delta n) - \mathbf{z}_p^{(k+1)} \|_2^2 \) which is derived using classical differential rules.

Specifically, we have that

\[
\nabla \mathcal{F}(\delta n) = \sum_{p=1}^{P} \text{Re} \left( \mathbf{J}_{\mathbf{H}_p}(\delta n) (\mathbf{B}_p(\delta n) - \mathbf{z}_p^{(k+1)}) \right),
\]

where \( \mathbf{J}_{\mathbf{H}_p}(\delta n) \) is the Jacobian matrix of the BPM forward model. It is computed efficiently by back-propagation as in [6].

Moreover, to reduce the computational cost, we compute the gradient only from a subset of angles \( L < P \). We choose the angles such that they are equally spaced and increment them at each FISTA iteration. The computational complexity of \( \nabla \mathcal{F}(\delta n) \) for one angle corresponds to the cost of \( 6N_c \) FFTs of size \( N_c \).

We implemented Algorithm 1 using the GlobalBioIm library [18].

4. NUMERICAL EXPERIMENTS

4.1. Simulated data

We simulated intensity measurements using a nonlinear accurate forward model [19]. The square area \( \Omega = 33 \lambda \times 33 \lambda \) includes the sample and the sensors. The medium has a RI \( n_b = 1.33 \) (i.e., water). The setup is similar to the scheme in Figure 1. A cell-like phantom is included in a central area of size \( 16.5 \lambda \). As shown in Figure 2 (top left), the cell body and the two ellipses have a RI of \( 1.45 \), and \( 1.33 \), as a consequence of the missing cone. However, contrarily to the LFR solution, we can distinguish the two ellipses and the shape of the cell body. The reconstructed RI is also close to the true value. The reconstruction error is \( 6 \cdot 10^{-3} \). The proposed method compares well against BPMc (error \( 5.4 \cdot 10^{-3} \)) for which the phase was provided.

![Fig. 2. Simulated data and their reconstruction. From left to right: (top) the cell-like phantom and its associated noiseless intensity measurements; (middle) the solutions from FBP [21] and BPMc [6]; (bottom) the LFR solution [20], and the RI distribution recovered by the proposed method. The elongated ellipses are due to missing informations along the optical axis.](image)

Noisy measurements We simulated noisy measurements at three different noise levels. For each of them, we set the incident fields \( \{ \mathbf{u}_p^{(m)} \}_{p=1, P} \) such that \( | \mathbf{u}_p^{(m)} | = A \in \mathbb{R}_{>0} \) and simulated the resulting intensity measurements. We considered three scenarios with \( A = 1.75, 3 \) and 5. Then, these measurements were corrupted using a Poisson distribution. The resulting SNR are 5.32, 9.77 and 14.13 dB, respectively. Simulated measurements are shown in Figure 3 (top line). The regularizations were set to \( \tau = 10^{-6} \cdot \| y_{/2} \|_2^2 \) for all noise levels.

As shown in Figure 3 (bottom line), the proposed method is still able to recover the shape of the cell and the ellipses. The reconstruction errors are \( 9.47 \cdot 10^{-3}, 8.07 \cdot 10^{-3} \) and 6.17 \cdot 10^{-3} for \( A = 1.75, 3 \) and 5, respectively. Despite the noise, we can still distinguish the different elements of the phantom, which demonstrates the robustness of the method.

4.2. Experimental data

We validated our method on experimental data. Holographic measurements were collected using a standard Mach-Zehnder interferometer, which relies on off-axis digital holography (\( \lambda = 450 \) nm). The sample was the cross-section of two fibres immersed in a medium of RI \( n_b = 1.525 \) (oil). We obtained \( P = 160 \) views ranging from \(-\frac{\pi}{4}\) to \(\frac{3\pi}{4}\). The RI variation is negative \( \delta n \in \mathbb{R}_{<0} \). The reconstructed area is \( \Omega = 38 \lambda \times 97 \lambda \). We compare the performance of the proposed method with BPMc. The latter and Algorithm 1 were
initialized with the solutions of the Rytov based-backpropagation [3] and LFR respectively.

The FISTA step size was set at $\gamma = 0.2/\|y_{P/2}\|_2^2$ for BPMc and our method. We set the penalty parameter to $\rho = 2.5$ for Algorithm 1. The regularization parameter $\tau$ was tuned manually.

As shown in Figure 4, both BPMc and the proposed method are able to reconstruct the cross-section of the two fibres. Although the phase is missing, our method reaches performances similar to BPMc.

5. CONCLUSION

We have proposed a method to reconstruct a map of refractive index (RI) from intensity-only measurements. It is a non-trivial extension from complex to amplitude-only of a state-of-the-art method for RI reconstruction from holographic measurements. We have combined proximity operators for phase retrieval with an efficient RI reconstruction pipeline. Using an adequate splitting of the problem, our method can cope with different noise models and regularizers. We showed its robustness to noise and to the limited-angle acquisition settings that are the main difficulties for biological imaging.
